Motivation

Definition

T(G) = maximum number of edge-disjoint spanning trees in G.

Example

$$T(G)=2.$$

Trivial upper bound

$$T(G) \leq \min \left\{ \delta, \lfloor \frac{\bar{d}}{2} \rfloor \right\},$$

where

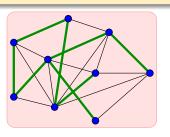

$$\frac{\bar{d}}{2} = \frac{m}{n-1}.$$

An application

Definition

T(G) = maximum number of edge-disjoint spanning trees in G.

Example

$$T(G)=2.$$

Trivial upper bound

$$T(G) \leq \min\left\{\delta, \left\lfloor \frac{\bar{d}}{2} \right\rfloor\right\},$$

where

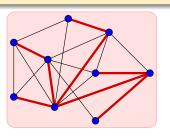

$$\frac{\bar{d}}{2} = \frac{m}{n-1}.$$

An application

Definition

T(G) = maximum number of edge-disjoint spanning trees in G.

Example

$$T(G)=2.$$

Trivial upper bound

$$T(G) \leq \min\left\{\delta, \lfloor \frac{\bar{d}}{2} \rfloor\right\}$$
,

where

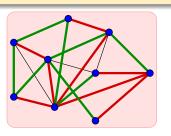

$$\frac{\bar{d}}{2} = \frac{m}{n-1}.$$

An application

Example

$$T(G)=2.$$

Trivial upper bound

$$T(G) \leq \min \left\{ \delta, \lfloor \frac{\bar{d}}{2} \rfloor \right\},$$

where

$$\frac{\bar{d}}{2} = \frac{m}{n-1}.$$

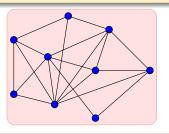

An application

Arboricity

Definition

A(G) = minimum number of spanning trees covering all edges of G; = minimum number of forests decomposing E(G).

Example

$$A(G) = 3.$$

Trivial lower bound

$$A(G) \geq \left\lceil \frac{\bar{d}}{2} \right\rceil$$
, where $\frac{\bar{d}}{2} = \frac{m}{n-1}$.

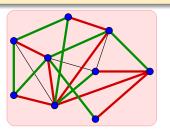

Some applications

Measure of density of subgraphs; k-orientability; load balancing.

Arboricity

Definition

A(G) = minimum number of spanning trees covering all edges of G; = minimum number of forests decomposing E(G).

Example

$$A(G) = 3.$$

Trivial lower bound

$$A(G) \geq \left\lceil \frac{\bar{d}}{2} \right\rceil$$
, where $\frac{\bar{d}}{2} = \frac{m}{n-1}$.

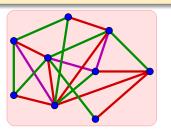

Some applications

Measure of density of subgraphs; k-orientability; load balancing.

Problem and previous results

Theorem (Palmer, Spencer '95)

$$T(\mathscr{G}(n,p)) = \delta$$
 a.a.s., for δ constant $(p \sim \log n/n)$.

Theorem (Catlin, Chen, Palmer '93)

$$\begin{cases} T(\mathscr{G}(n,p)) = \lfloor \frac{\bar{d}}{2} \rfloor \\ A(\mathscr{G}(n,p)) = \lceil \frac{\bar{d}}{2} \rceil \end{cases} \quad \text{a.a.s.,} \quad \text{for } p = C(\log n/n)^{1/3}.$$

Theorem (Chen, Li, Lian '13+)

$$T(\mathscr{G}(n,p)) = \delta$$
 a.a.s., for $p \le 1.1 \log n/n$; $T(\mathscr{G}(n,p)) < \delta$ a.a.s., for $p \ge 51 \log n/n$.

Question (Chen, Li, Lian)

What's the smallest p such that $T(\mathcal{G}(n,p)) < \delta$?

Our results (i)

Theorem

For every $p = p(n) \in [0,1]$, a.a.s. $T(\mathscr{G}(n,p)) = \min \left\{ \delta, \lfloor \frac{\bar{d}}{2} \rfloor \right\}$. (Same holds throughout the random graph process.)

Theorem

Let $\beta = 2/\log(e/2) \approx 6.51778$.

• If
$$p = \frac{\beta \left(\log n - \frac{\log \log n}{2}\right) - \omega(1)}{n-1}$$
, then a.a.s. $\delta \leq \left\lfloor \frac{\bar{d}}{2} \right\rfloor$ in $\mathscr{G}(n, p)$.

• If
$$p = \frac{\beta \left(\log n - \frac{\log \log n}{2}\right) + \omega(1)}{n-1}$$
, then a.a.s. $\delta > \lfloor \frac{\bar{d}}{2} \rfloor$ in $\mathscr{G}(n, p)$.

(Same holds throughout the random graph process.)

Threshold for
$$T(\mathscr{G}(n,p)) = \begin{cases} \delta \\ \lfloor \frac{\bar{d}}{2} \rfloor \end{cases}$$
 at $p \sim \beta \frac{\log n}{n}$.

- - - - - -

Our results (ii)

Theorem

- ullet If p=O(1/n), then a.a.s. $Aig(\mathscr{G}(n,p)ig)\in\{k,k+1\}$, where $k>rac{ar{d}}{2}.$
- If $p = \omega(1/n)$, then a.a.s. $A(\mathscr{G}(n,p)) \in \{\lceil \frac{\bar{d}}{2} \rceil, \lceil \frac{\bar{d}}{2} \rfloor + 1\}$.

For most values of $p = \omega(1/n)$, a.a.s. $A(\mathscr{G}(n,p)) = \lceil \frac{\bar{d}}{2} \rceil$.

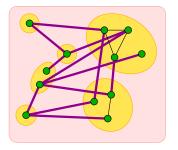

(Same holds throughout the random graph process.)

Corollary

Threshold for k-orientability of $\mathscr{G}(n,m)$ for $k \to \infty$ at $m \sim kn$.

Tutte and Nash-Williams

 \mathcal{P} partition of V(G); $m(\mathcal{P}) = \text{number of edges in } E(G)$ with ends in distinct parts of \mathcal{P} .

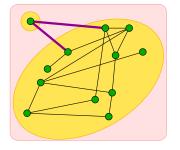

Theorem (Tutte '61; Nash-Williams '61)

A graph G has t edge-disjoint spanning trees iff every partition \mathcal{P} of V(G) satisfies $m(\mathcal{P}) \geq t(|\mathcal{P}|-1)$.

T(G) is given by the smallest ratio $\left\lfloor \frac{m(\mathcal{P})}{|\mathcal{P}|-1} \right\rfloor$.

Tutte and Nash-Williams

Proof STP number $\mathcal{G}(n, p)$

Trivial range: $p \le 0.9 \frac{\log n}{n}$

$$\delta = T = 0$$
.

Interesting range: $p \ge 0.9 \frac{\log n}{n}$

Consider set of properties \mathcal{A} (degrees, expansion, density...).

Prove that

- $\mathscr{G}(n,p)$ satisfies \mathcal{A} , a.a.s.
- ullet \mathcal{A} implies that $\forall \mathcal{P}, \quad ext{the ratio } rac{m(\mathcal{P})}{|\mathcal{P}|-1} \geq \left\{ rac{\delta,}{d/2}.
 ight.$

Then, a.a.s. $T(\mathscr{G}(n,p)) = \min\{\delta, \bar{d}/2\}.$

Note: When $\delta > \bar{d}/2$, we have a full decomposition of edges.

◆ロト ◆回 ト ◆ 恵 ト ◆ 恵 ・ り Q ○

Proof Arboricity $\mathscr{G}(n,p)$ — Range $p = \omega(1/n)$

Range $p = \omega(1/n)$

Create G' from $G = \mathcal{G}(n, p)$:

Add o(n) new edges to $\mathcal{G}(n,p)$ so that

- $\delta' > \bar{d}'/2$;
- ullet properties ${\cal A}$ are satisfied;
- $n-1 \mid m'$.

Then
$$T(G') = \overline{d}'/2 = \frac{m'}{n-1} = A(G')$$
 and

$$A(\mathscr{G}(n,p)) \in \left\{ \left\lceil \frac{m}{n-1} \right\rceil, \left\lceil \frac{m}{n-1} \right\rceil + 1 \right\}.$$

Proof Arboricity $\mathscr{G}(n,p)$ — Range p = O(1/n)

Theorem (Nash-Williams '64)

Edges of G can be covered by t forests iff for every non-empty $S \subseteq V(G)$ we have $|E[S]| \le t(|S|-1)$.

$$A(G) = \max_{\emptyset \neq S \subseteq V(G)} \left\lceil \frac{|E[S]|}{|S|-1} \right\rceil, \qquad \text{(where } 0/0 := 0\text{)}.$$

k-core

Largest subgraph with minimum degree k.

Theorem (follows from Hakimi '65 + Cain, Sanders, Wormald '07)

For k > 2.

if the density of the (k+1)-core of $\mathcal{G}(n,p)$ is at most k+o(1), then a.a.s.

 $\mathcal{G}(n,p)$ has no subgraph with density more than k+o(1).

ISU 2014

Proof Arboricity $\mathscr{G}(n,p)$ — Range p = O(1/n)

Summary of the argument

If $p \le 1/n$, then $A \in \{1, 2\}$ (easy).

If p > 1/n:

- Find k such that
 - the (k+1)-core of $\mathcal{G}(n,p)$ has density at most k+o(1);
 - the k-core of $\mathcal{G}(n,p)$ has density greater than (k-1).
- Then the densest subgraph of $\mathcal{G}(n,p)$ has density > (k-1) and $\leq k + o(1)$.
- So $A \in \{k, k+1\}$.

Further work

- Extend results to random hypergraphs (easy).
- Extend results to other families of random graphs (work in progress for random geometric graphs, sparse graphs with a fix degree sequence).
- Study other graph parameters with similar characterisations following from matroid union (work in progress for random directed graphs).

Thank you
